Abstract

Background: Data sciences solutions such as artificial intelligence are increasing. A common challenge is identifying appropriate scenarios or "use cases" for data sciences implementation. Implementation frameworks are primarily generated from a theoretical or single institution based perspectives, highlighting the need for a multi-institutional experience to reveal patterns within successful implementations.

Objective: To describe successful and unsuccessful approaches to identify scenarios for data science implementations within healthcare settings and to provide recommendations for future scenario identification procedures.

Methods: Representatives from seven Toronto academic healthcare institutions participated in a one-day workshop. Each institution was asked to provide an introduction to their clinical data science program and to provide an example of a successful and unsuccessful approach to scenario identification at their institution. Using content analysis, common observations were summarized.

Results: Observations were coalesced to idea generation and value proposition, prioritization, approval and champions. Successful experiences included promoting a portfolio of ideas, articulating value proposition, ensuring alignment with

Abstract

Background: Data sciences solutions such as artificial intelligence are increasing. A common challenge is identifying appropriate scenarios or "use cases" for data sciences implementation. Implementation frameworks are primarily generated from a theoretical or single institution based perspectives, highlighting the need for a multi-institutional experience to reveal patterns within successful implementations.

Objectives: To describe successful and unsuccessful approaches to identify scenarios for data science implementations within healthcare settings and to provide recommendations for future scenario identification procedures.

Materials and Methods: Representatives from seven Toronto academic healthcare institutions participated in a one-day workshop. Each institution was asked to provide an introduction to their clinical data science program and to provide an example of a successful and unsuccessful approach to scenario identification at their institution. Using content analysis, common observations were summarized.

Results: Observations were coalesced to idea generation and value proposition, prioritization, approval and champions. Successful experiences included promoting a portfolio of ideas, articulating value proposition, ensuring alignment with organization priorities, ensuring approvers can adjudicate feasibility and identifying champions willing to take ownership over the projects.

Conclusion: Based on academic healthcare data science program experiences, we provided recommendations for approaches to identify scenarios for data science implementations within healthcare settings.

Keywords: machine learning, data sciences, healthcare, use case, scenario

Introduction

Healthcare institutions rely upon data to influence decision making at the organizational level and to improve patient outcomes.[1] Examples range from simple reports to rule- or machine learning- (ML) based algorithms. Constraints to using data to drive decision making include, but are not limited to, challenges with data access, security and privacy restrictions, need to ensure patient safety and address ethical aspects, fragmented data ecosystems and funding/resource limitations. These remain open challenges in implementing data science approaches. It is important to identify solutions to these challenges to accelerate data science-directed advancements in healthcare.

Scenario identification (or "use case" identification) is a specific challenge for data sciences in the clinical context because of the need to curate solutions and optimize use of scarce resources. Scenario refers to both the operational or clinical problem in addition to the specific setting in which the data will be applied. For example, sepsis is an example of a clinical problem whereas sepsis prediction during admission to a general ward is an example of a scenario.

There are several papers that have described frameworks for healthcare institutions to develop and implement data science solutions, including ML.[2-8] However, most propose solutions that are generated from a theoretical or a single institution perspective. In contrast, we hypothesized that building upon the experiences of several academic health sciences institutions implementing data science solutions would reveal more general patterns associated with successful implementations. Our objective was to describe successful and unsuccessful approaches to identify scenarios for data science implementations within healthcare settings and to provide recommendations for future scenario identification procedures.

Methods

The Data Sciences Institute (DSI) is a multi-divisional, tri-campus and multidisciplinary hub for data science activity at the University of Toronto. The DSI mission is to accelerate the impact of data sciences across disciplines to address pressing societal questions and drive positive social change. They define data sciences as the science of collecting, manipulating, storing, visualizing, learning from and extracting useful information from data in a reproducible, fair and ethical way. DSI partners with seven healthcare institutions in Toronto and collaborates with the Temerty Faculty of Medicine Centre for Artificial Intelligence Education and Research in Medicine (T-CAIREM). T-CAIREM supports a community of over 1,500 members focused on research, education and infrastructure for artificial intelligence in health care.

The DSI and T-CAIREM co-hosted a one-day in-person workshop with representation from the following seven DSI-affiliated healthcare institutions: Baycrest Centre, Holland Bloorview Kids Rehabilitation Hospital, Mount Sinai Hospital, The Hospital for Sick Children, Unity Health Toronto, University Health Network and Women's College Hospital. The workshop was held at the DSI offices on April 5, 2024. Each institution was asked to provide a brief introduction to their data science program and to provide an example of a successful and unsuccessful approach to scenario identification at their institution. Each presentation was followed by a question and answer period.

Once all presentations were completed, attendees first outlined some general observations about the potential utility and limitations of experience reflections from this group. Next, we outlined general considerations required to develop and implement data science solutions in healthcare, where the focus of the present meeting was to discuss

scenario identification approaches. Finally, the discussion centered on common observations across experiences with successful and unsuccessful approaches to identify scenarios for data science implementations.

Notes were taken during the meeting by one author (HL). Using the presentations themselves and the meeting notes, content analysis[9] was performed by a single reviewer (LS). These results were evaluated and revised by a second reviewer (HL). If discrepancies were identified, the two reviewers met to come to consensus. Summarized results were then reviewed and confirmed by all authors.

Results

We observed that sharing of experiences was useful for learning and collaborating, with the potential to accelerate each hospital's program by leveraging insights made at other institutions. We also observed that a synthesis of approaches that are consistently successful and those that are consistently unsuccessful is likely to be generalizable across many settings. High-level approaches are more likely to be generalizable rather than the specific plans to implement, which will typically be driven by local circumstances.

	level at decision-making	solution or be	responsibility for project
	table as well as	accountable for poor	success or failure
	implementation	outcomes	Requires representation from
	champions		target users
	Willing to take		
	ownership		
	Knowledgeable		

Table 1 describes the general considerations required to develop and implement data science solutions in healthcare, where scenario identification was the focus of the workshop. Table 2 describes common observations with successful and unsuccessful approaches to identify scenarios. Examples were shown by idea generation and value proposition, prioritization, approval and champions. Table 2 also provides recommendations related to each of these areas.

Idea Generation and Value Proposition: In the context of scenario identification, we recommend that there is a mechanism, within an organization, that allows many ideas to be proposed for downstream prioritization. Ideas can be generated and shaped from a wide variety of sources spanning operational and clinical needs to an individual clinician's or researcher's ideas. To address unmet needs, an operational perspective that prioritizes aligned innovation or improvement is required. We also recognized the importance of balancing risk, and that some risk tolerance should be promoted as long as it is monitored and it is balanced against potential benefit. A critical component of scenario identification is clear articulation of the value proposition and anticipated return on investment for scenario development and deployment. In identifying scenarios, it is important to use local data to ensure problems or outcomes are sufficiently common to justify institutional investment.

An unsuccessful example was when the same scenario was being proposed by multiple groups for the same target user. These different groups might represent different operational, clinical or research perspectives. Identifying duplicative siloed efforts is important; target user may be in the best position to recognize and reconcile them.

Prioritization: It is important to distinguish between approval to explore in the research phase vs. approval to implement. We suggest that if there are no or limited resource implications, researchers should be encouraged to innovate and identify solutions as freely as possible, while adhering to regulatory and privacy frameworks. Prioritization should occur at the point of clinical implementation, or when there are implications for institutional resources or impact.

Prioritization is a critical process that should consider limited resources, organizational strategy, prioritized improvement efforts and overall cost-benefit. While it is important that prioritization aligns with operational and clinical needs, how to actually prioritize specific projects and who performs the prioritization will likely differ between

institutions. Institutions should promote alignment of research energy and culture with problems prioritized by clinicians and leaders where feasible.

Approval: The mechanism to approve scenarios was particularly heterogeneous. The group agreed that the approval process must take into account what operational or clinical scenarios are important to the organization as well as determine the feasibility of a data science approach. The approval process must also be able to assess likely return on investment. Successful examples included single or a small number of knowledgeable individuals to approve scenario identification. An unsuccessful example was when large executive groups made the decision of which data science solutions were to proceed as they may not have the requisite knowledge to be able to judge clinical impact or data science feasibility. With large groups, there may be few members who engage in the discussion or make the effort to fully understand the proposal, its feasibility and likelihood for success.

Champions: It is important that there is an individual or group of individuals who are willing to take ownership over the project implementation and to be accountable for the measured success and failure. This ownership must occur throughout the various stages of the project. These individuals are likely to be at the executive level. In contrast, projects were not successful when no one was willing to take responsibility for them.

Discussion

We summarize successful and unsuccessful approaches to identify scenarios for data science implementations in healthcare. Observations were coalesced to idea generation and value proposition, prioritization, approval and champions. Successful experiences included promoting a portfolio of ideas, articulating value proposition, ensuring alignment with organization priorities, ensuring approvers can adjudicate feasibility and identifying champions willing to take ownership over the projects.

While these observations arose out of real-world experiences, we recognize that there are many appropriate ways to generate and approve scenarios and our observations are unlikely to be applicable to all settings. Nonetheless, despite different institutions and patient populations (e.g. spanning neonatal to geriatric), observed commonalities support some generalizability. We hope that sharing our successes and challenges can contribute to the broader discourse around data-driven decision making in healthcare.

Scenario identification, prioritization and approval is only one step in data science implementations in healthcare. Future workshops could focus on identifying shared experiences related to other aspects such as data access and governance as an example. Another important aspect that warrants further exploration is approaches that promote successful implementations and sustainability post deployment.

The strength of this report lies in the number and heterogeneity of contributing organizations. However, this report is limited as all institutions belonged to the same umbrella networks, namely DSI and T-CAIREM. Factors that influence decisions at academic centers in Toronto may be different than in other places. Further, despite the number and heterogeneity of organization involved, they do not cover all possible types of healthcare contexts and thus continued analysis of diverse settings will be beneficial.

In summary, based on academic healthcare data science program experiences, we provided recommendations for approaches to identify scenarios for data science implementations within healthcare settings. Future efforts should focus on other

requirements to successfully deploy data sciences solutions in healthcare.
